

Architectural Definition of Intrinsic Dimensions

What physically defines the space an image requests from the browser before CSS intervenes?

Raster Assets (JPEG/PNG)

⊕ Parsed Payload

Width: 4000 px
Height: 3000 px
Aspect Ratio: 4:3

The Immutable Pixel Grid

For raster images, intrinsic dimensions are a **physical memory reality** encoded in the file header. The browser reads these bytes *first*. Before the image even finishes decoding, the rendering engine allocates a rigid, unyielding rectangle of exactly 4000×3000 CSS pixels for this asset.

Vector Assets (SVG)

The Declarative Coordinate Window

Vectors are mathematically infinite. Their intrinsic dimensions are **purely declarative**, established by the root width and height attributes (which map to CSS pixels), or derived from the aspect ratio of the viewBox. Without these specific attributes, an SVG has *no inherent physical size at all*!

The "Replaced Element" Boundary

Tags like `<img>` and `<video>` are **Replaced Elements**. CSS does not render their internal contents. CSS merely provides a bounding box to an external decoder. *If CSS provides no active constraints, the bounding box forcefully defaults to the external asset's Intrinsic Dimensions.*
