

Architectural Integration: Inline <svg>

Seamless DOM Integration Permitting Responsive Art Direction

1. Unified Parser Tree

When SVG code is written directly into the HTML document, the HTML5 parser tokenizes elements like `<path>` and inserts them natively into the primary DOM tree alongside standard HTML tags.

2. Direct CSSOM Penetration

Because there is no encapsulation wall, the Global CSSOM engine can map rules perfectly. Selectors traverse the tree seamlessly, allowing vector points to react to pseudo-classes like `:hover` or JavaScript event listeners.

3. True Art Direction

This architecture enables responsive art direction. Media queries in your main CSS file can selectively hide layers, change viewports, or alter stroke properties to optimize the SVG for different screen sizes.
